Analyze the Boston Housing dataset and apply appropriate

Regression Technique

Date of Performance: 27/07/23

Date of Submission: 17/08/23

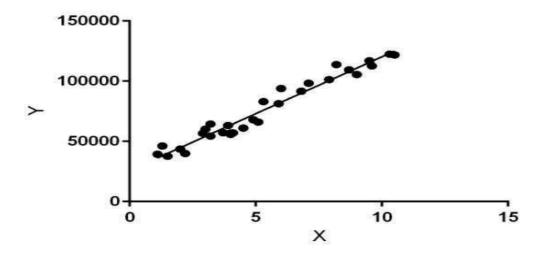

Aim: Analyze the Boston Housing dataset and apply appropriate Regression Technique.

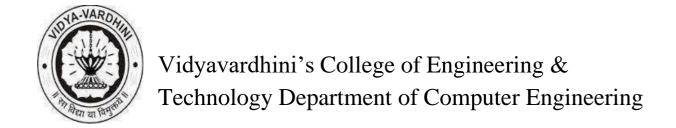

Objective: Ablility to perform various feature engineering tasks, apply linear regression on the given dataset and minimise the error.

Theory:

Linear Regression is a machine learning algorithm based on supervised learning. It performs a regression task. Regression models a target prediction value based on independent variables. It is mostly used for finding out the relationship between variables and forecasting. Different regression models differ based on — the kind of relationship between dependent and independent variables they are considering, and the number of independent variables getting used.

Linear regression performs the task to predict a dependent variable value (y) based on a given independent variable (x). So, this regression technique finds out a linear relationship between x (input) and y(output). Hence, the name is Linear Regression.

In the figure above, X (input) is the work experience and Y (output) is the salary of a person. The regression line is the best fit line for our model.

Dataset:

The Boston Housing Dataset

The Boston Housing Dataset is a derived from information collected by the U.S. Census Service concerning housing in the area of Boston MA. The following describes the dataset columns:

CRIM - per capita crime rate by town

ZN - proportion of residential land zoned for lots over 25,000 sq.ft.

INDUS - proportion of non-retail business acres per town.

CHAS - Charles River dummy variable (1 if tract bounds river; 0 otherwise)

NOX - nitric oxides concentration (parts per 10 million)

RM - average number of rooms per dwelling

AGE - proportion of owner-occupied units built prior to 1940

DIS - weighted distances to five Boston employment centres

RAD - index of accessibility to radial highways

TAX - full-value property-tax rate per \$10,000

PTRATIO - pupil-teacher ratio by town

B - 1000(Bk - 0.63)² where Bk is the proportion of blacks by town

LSTAT - % lower status of the population

MEDV - Median value of owner-occupied homes in \$1000's

Code:

import numpy as np

import pandas as pd

import os

print(os.listdir("../input"))

from pandas import read_csv

column_names = ['CRIM', 'ZN', 'INDUS', 'CHAS', 'NOX', 'RM', 'AGE', 'DIS',

'RAD', 'TAX', 'PTRATIO', 'B', 'LSTAT', 'MEDV']

data=read_csv('../input/housing.csv',header=None,delimiter=r"\s+",names=column_names)

print(data.head(5))

import seaborn as sns

import matplotlib.pyplot as plt

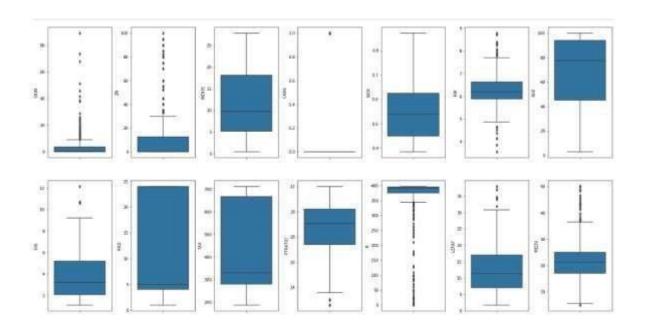

from scipy import stats

fig, axs = plt.subplots(ncols=7, nrows=2, figsize=(20, 10))

index = 0

axs = axs.flatten()
for k,v in data.items():
 sns.boxplot(y=k, data=data, ax=axs[index])
 index += 1
plt.tight_layout(pad=0.4, w_pad=0.5, h_pad=5.0)

```
for k, v in data.items():
```

q1 = v.quantile(0.25)

q3 = v.quantile(0.75)

irq = q3 - q1

 $v_{col} = v[(v \le q1 - 1.5 * irq) | (v >= q3 + 1.5 * irq)]$

 $perc = np.shape(v_col)[0] * 100.0 / np.shape(data)[0]$

print("Column %s outliers = %.2f%%" % (k, perc))

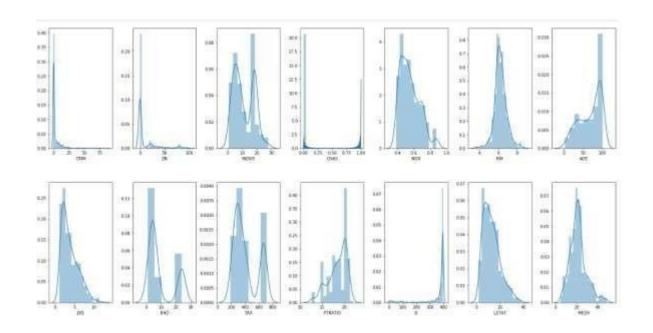

index += 1

Vidyavardhini's College of Engineering & Technology Department of Computer Engineering

```
data = data[~(data['MEDV'] >= 50.0)]
print(np.shape(data))

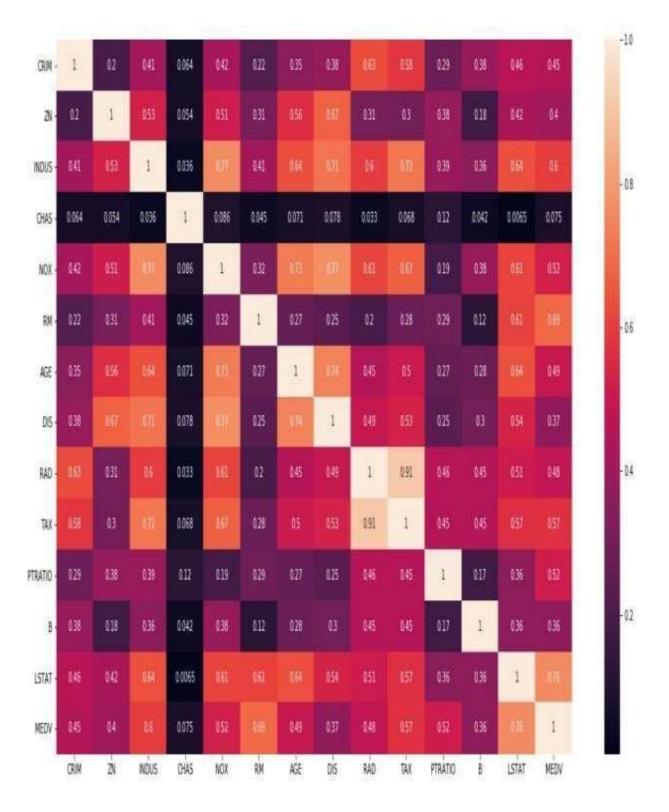

fig, axs = plt.subplots(ncols=7, nrows=2, figsize=(20, 10))
index = 0
axs = axs.flatten()
for k,v in data.items():
    sns.distplot(v, ax=axs[index])
```

plt.tight_layout(pad=0.4, w_pad=0.5, h_pad=5.0)

plt.figure(figsize=(20, 10))
sns.heatmap(data.corr().abs(), annot=True)

```
from sklearn import preprocessing
min_max_scaler = preprocessing.MinMaxScaler()
column_sels = ['LSTAT', 'INDUS', 'NOX', 'PTRATIO', 'RM', 'TAX', 'DIS',
'AGE']
x = data.loc[:,column\_sels]
y = data['MEDV']
x=pd.DataFrame(data=min_max_scaler.fit_transform(x),
columns=column_sels)
fig, axs = plt.subplots(ncols=4, nrows=2, figsize=(20, 10))
index = 0
axs = axs.flatten()
for i, k in enumerate(column_sels):
  sns.regplot(y=y, x=x[k], ax=axs[i])
plt.tight_layout(pad=0.4, w_pad=0.5, h_pad=5.0)
y = np.log1p(y)
for col in x.columns:
  if np.abs(x[col].skew()) > 0.3:
    x[col] = np.log1p(x[col])
from sklearn import datasets, linear_model
from sklearn.model_selection import cross_val_score
from sklearn.model_selection import KFold
import numpy as np
1_regression = linear_model.LinearRegression()
kf = KFold(n_splits=10)
min max scaler = preprocessing.MinMaxScaler()
```

x_scaled = min_max_scaler.fit_transform(x)

scores=cross_val_score(l_regression,x_scaled,y,cv=kf,scoring='neg_mean_squa red_error')

print("MSE: %0.2f (+/- %0.2f)" % (scores.mean(), scores.std()))

MSE: -0.04 (+/- 0.04)

Conclusion:

Features have been chosen to develop the model:

- 1. CRIM Per capita crime rate by town
- 2. CHAS Charles River dummy variable (1 if tract bounds river; else 0)
- 3. NOX Nitric oxides concentration (parts per 10 million)
- 4. RM Average number of rooms per dwelling
- 5. DIS weighted distances to five Boston employment centres
- 6. RAD Index of accessibility to radial highways
- 7. TAX Full-value property-tax rate per \$10,000
- 8. PTRATIO Pupil-teacher ratio by town
- 9. LSTAT Lower status of the population

Mean Squared Error calculated:

- ➤ Calculated Mean Squared Error: 0.04 (+/- 0.04)
- ➤ The Mean Squared Error measures how close a regression line is to a set of data points.
- ➤ Lesser the Mean Squared Error refers to Smaller is the error and Better the estimator.
